# Overview of Lidskjalv

Lidskjalv [\[1\]](#) is an platform independent object-oriented user interface construction framework for constructing user interfaces that are easily portable between the Macintosh window system, the X Window System (based on Motif Widgets), and the Microsoft Windows (Windows NT, Windows 2000, Windows 98, or Windows 95).

This document contains the object-oriented model for Lidskjalv, along with an overview of the interface files for Lidskjalv.

The Lidskjalv model is based on previous experiences in developing object-oriented user interface construction frameworks for the Macintosh window system, and the X Window System (based on Athena and Motif Widgets). It has been an important design criterion to make a model that deals with the construction of portable user interfaces in such a way that the details of the look-and-feel of the Lidskjalv applications will conform to the standardised look-and-feel at the specific platform; i.e. the interface will appear to the user as a genuine Motif interface when running in a Motif environment, and will appear as a genuine Macintosh application when running in a Macintosh environment, etc. However, not all issues can be dealt with without the co-operation from the application programmer. To give an example: if the application programmer decides that the windows in the application should contain individual menubars, there is no way this application can conform with the Macintosh User Interface Guidelines. However, Lidskjalv will allow the application programmer to specify individual window menubars on a Macintosh. However, the application programmer might use other facilities of Lidskjalv to deal with this issue of window-specific menubars, such that the code is purely portable across look-and-feel.

Lidskjalv defines abstractions for all commonly used interface objects, such as window, menubar, menu, button, text fields, figure items, scrolling lists, etc. Each interface object takes care of the interactions related to itself, and it is the responsibility of the entire framework to ensure that the user interactions (such as mouse button presses, key presses, etc.) are taken care of and converted internally into invocations of virtual procedures of the appropriate interface object - that is, no application programmer needs to handle user interaction at the event level of the underlying platform.

Lidskjalv is realised in the form of a class, `guienv`, whose instance acts as the framework for the user interface, taking care of all platform dependent event handling, etc.

---

[1] Lidskjalv is the name of the Odin's high throne, from which he is able to look into all Worlds and see everything that happens.

---

# The Lidskjalv Libraries

The Lidskjalv libraries consists of 15 libraries (fragments):

- guienv
- stddialogs
- control
- fields
- figureitems
- scrolllist
- graphmath
- graphics
- styledtext
- guenvactions
- controlsactions
- fieldsactions
- guenvall
- guenvsystemenv

The guienv library defines the basic facilities of the Lidskjav framework (as described above). All Lidskjav programs must include at least the guienv fragment.

The stddialogs library includes a few predefined patterns for simple, standard dialogs, such as fileSelectionDialog.

The control library includes facilities for specifying control interfaceObjects (such as buttons etc.) as described above.

The fields library includes facilities for specifying field interfaceObjects (such as static text fields, editable textfields, etc.)

The figureitems library includes facilities for specifying basic graphics interfaceObjects (such as lines, ovals, etc.)

The scrolllist library includes facilities for specifying scrolling interfaceObjects (such as scrolling lists etc.)

The graphmath library includes facilities for graphics computations, such as definition and manipulation of point, rectangle, etc.)

The graphics library includes facilities for simple graphics, such as line drawings.

The styledtext library includes facilities for working with styled text (i.e text in different fonts and styles). Currently only available on Macintosh platforms.

The guenvactions library defines the actions related to the interfaceObjects, defined in the guienv library (more on actions later).

The controlsactions library defines the actions related to the interfaceObjects, defined in the controls library.

The fieldssactions library defines the actions related to the interfaceObjects, defined in the fields library.

The guienvall library is a very simple library, including all the above libraries. Used for easy access to the entire suite of facilities in guienv.

The guienvsystemenv library is a very simple library that enables concurrency and guienv to work perfectly together.

# Utilities Libraries

Besides these libraries, the Lidskjalv user interface framework includes a number of utility libraries. These libraries are located in the utils sub-directory of the Lidskjalv directory tree. It should be noted, that these libraries contains many very useful facilities, but these libraries are not described in this manual. Please refer to the [utilities interface files](#) for details of the very many useful patterns.

# Multimedia Libraries

Lidskjalv contains two important libraries for controlling multimedia devices (CD players and QuickTime movies) on the Windows and Macintosh platforms (Unix platform not supported). These facilities are placed in the multimedia sub-directory of the Lidskjalv directory tree. Please refer to the [multimedia interface files](#) for details of these useful patterns.

# OpenGL Libraries

Lidskjalv contains libraries for making OpenGL graphics. These facilities are placed in the openGL sub-directory of the Lidskjalv directory tree. It should, however, be noted that these libraries are not fully developed, and tested, and is included in this release 'as-is'. Please refer to the [OpenGL interface files](#) for details of these useful patterns.

# Chapter 1: The guienv Library

Guienv is the most basic library of the Lidskjalv libraries. Guienv implements the most often used elements of a graphical user interface, such as menus, windows, etc. along with a lot of supporting facilities.

The prime elements of guienv is the definition of the menu system and the facilities for defining windows along with facilities for handling the events (such as mouse button press), originating from the user interface (menus, windows, etc.).

The most important classes, defined in guienv are:

- `interfaceObject` is the root of the hierarchy of interface components in Lidskjalv.
- `menuBar` is a class, defining the facilities for defining menubars. The global menubar (if any) is accessed through the `applicationMenubar` attribute. `StandardMenubar` defines the standard menubar, used by most applications.
- `menu` is a class, defining the facilities for menus, both menus of menubars, menus associated with buttons, and popup menus.
- `window` defines the facilities for defining and manipulation windows.

The rest of the attributes defines various other facilities for accessing different other aspects of the window system.

The most important class in Lidskjalv is `interfaceObject`. It defines the facilities available for controlling all interface components in guienv.

`interfaceObject` implements the basic facilities for all interaction:

- `open` and `close` is invoked when the `interfaceObject` is opened and closed on the screen.
- `enableEventType` and `disableEventType` are used to control which interactions, this `interfaceObject` is willing to respond to (default is that all event types are enabled).
- Most attributes relate to event handling. `Event` is the superpattern for all event patterns (such as `mouseDown` and `refresh`). These events are invoked by the underlying system as the result of, e.g. user interactions.

Event handling in guienv is handled through defining virtual further bindings in which the actions to be executed as the result of an event, is specified. Each `interfaceObject` type defined a series of event virtuels in the eventhandler virtual pattern, and users of these `interfaceObjects` may then further bind this eventhandler, and in this further binding specify the actions to be executed for the particuler events, defined for that type of `interfaceObject`.

The basic eventhandler (defined in `interfaceObject`) defines the following events: `onMouseDown`, `onMouseUp`, `onKeyDown`, `onRefresh`, `onActivate`, and `onDeactivate`. Some of these events carry global information on the state of the keyboard and mouse.

In order to support more dynamic event handling, it is also possible dynamically to attach actions before or after the predefined actions for an event. This is done by specifying an instance of (a subpattern of) action and then either prepend or append it to the already attached actions (using the `prependAction` or `appendAction` operations). An action can be retracted again by the `deleteAction` operation.

Parallel to the event hierarchy is an action hierarchy. An action (e.g. `mouseDownAction` and `refreshAction`) can be associated with an event, such that the actions will be invoked either before or after the events itself. These actions are defined in separate libraries, see chapters 10-12.

In order to control the `interfaceObject`'s sensibility to individual event types, the operations `enableEventType` and `disableEventType` are available.

# Event handling

One of the strengths of the Lidskjalv libraries is the ease with which the event handling is conducted. Essentially, the Lidskjalv libraries takes care of all the details of the event dispatching and handling. The Lidskjalv libraries essentially converts all event occurrences into invocation of special virtual patterns within the appropriate user interface object (e.g. the one below the mouse pointer). In the Lidskjalv documentation, these virtual patterns are often referred to as the event patterns (or simply events). The application programmer only has to further bind these event patterns of the individual user interface objects to specify the actions to be taken in response to user interaction.

Lidskjalv - Reference Manual

[Mjølner](#)  
[Informatics](#)

.

.

# Menu facilities

The menu facilities are centred around the concept of menubars. In `guienv`, there may be any number of menubars: an application menubar, and a menubar associated with each window. In both cases, these menubars are specified as instances of the `menubar` pattern:

`menubar` implements the facilities for defining menubars.

- `append`, `delete` and `clear` are used for manipulating the menus in the menubar.
- `appendMenubar`, `replaceMenubar`, and `deleteMenubar` is used for manipulating a menubar as part of another menubar (e.g. appending all menus in one menubar to another menubar).
- `scan` facilitates scanning all menus associated with this menubar.

The application menu can be specified by further binding the `menubarType` virtual. If a standard application menubar is what you want, just further bind to `standardMenuBar`.

`StandardMenubar` defines the following important attributes:

- `standardFileMenu` and `standardEditMenu` defines the standard file and edit menus. `fileMenu`, `theFileMenu` and `editMenu`, `theEditMenu` are facilities for specifying different file and edit menus.

The application menubar can be changed and accessed through the `applicationMenubar` attribute.

The individual menus in a menubar is specified as instances of the `pattern menu`. `menu` defines the following important attributes:

- `name` defines the name of this menu.
- `onSelect` is invoked when selecting in the menu. Further bind this attribute (defined in the local `eventhandler` virtual) to specify the actions to be executed when this menu is selected in the menubar.
- `menuItem` and `dynamicMenuItem` are used to define the individual menu items, and `action` is used to specify actions to be associated with dynamic menuitems (see later).
- `append`, `delete`, `clear` and `scan` are used for manipulating the menu items of this menu.
- `popUp` is used to pop-up this menu.
- `enable` and `disable` is used to control whether the menu is enabled or disabled in the menubar.

The `pattern menuItem` is the facility for defining the individual items in a menu. Most attributes (`name`, `key`, `checked`, etc.) define the visual appearance of the menu item. Besides the following important attributes are defined:

- `onStatus` is used to define when the menu item is selectable.
- `onSelect` is used to specify the actions to be executed when the menu item is selected.

- subMenu is used to attach an entire menu to a menu item (i.e. creating a hierarchical menu).

The separator pattern is a special menuItem that inserts a vertical line in the menu to separate groups of items.

The menuItem pattern assumes that the same actions always must be executed when a menu item is selected. If however, we want a more dynamic behaviour, the pattern dynamicMenuItem must be used. This pattern allows actions to be associated dynamically with the particular menu item. dynamicMenuItem defines the following important attributes:

- attach and detach is used to associate the actions with this dynamicMenuItem.

The actions to be associated with a dynamicMenuItem must be instances of the menuItemAction pattern.

# Window facilities

window defines the means for creating windows in applications. It defines the following important attributes:

- The events: `onAboutToClose`, `onActivate`, etc. are the facilities for specifying actions to be executed as consequence of user interactions.
- `theMenubar` and `menubarType` are the means for associating a menubar with this window. And `menubarVisible` controls whether the menubar should be visible.
- `title` is used for specifying the window title.
- `position`, `frame` and `size` are used to control the location of the window.
- `floating` controls whether this window will float on top of all other windows.
- `show` and `hide` is used to control the visibility of the window.
- `showModal` specifies that this window will be shown as a modal window.
- `bringToFront`, `bringBack` and `bringBehind` is used to control the stacking order of this window.
- `target` is used to control the keyboard focus within this window.
- `windowItem` is the central facility for defining the contents of windows. `WindowItems` can be attached to windows (more details later).
- `type` controls the appearance of the titlebar of the window: `palette`, `dialog` or `normal`.
- `canvas` is a subclass of `windowItem`, implementing a local coordinate system. Just as windows, more than one `windowItem` may be associated with a canvas. Canvas function as a mean for grouping `windowItems` within windows (or other canvasses).

`windowItem` is the central class for specifying the contents of windows (and canvasses). The contents of windows are one instance of `canvas`, simplifying the design.

- the events: `onVisibilityChanged`, `onFrameChanged`, `onFatherFrameChanged`, `onMouseUp`, etc. are the means for specifying actions to be executed as the consequence of user interactions (directly or indirectly).
- `father` is a reference to the canvas (and thereby possibly the window), this `windowItem` is associated with.
- `frame`, `position`, `move` and `size` is used to control the location of the `windowItem` within the father canvas.
- `bindLeft`, `bindRight`, `bindBottom` and `bindTop` is used to control the behaviour of this `windowItem` when the father canvas has changed frame.
- `show` and `hide` is used to control whether this `windowItem` is visible on its father canvas.
- `enable` and `disable` is used to control whether this `windowItem` reacts to mouse and keyboard interactions.
- `theCursor` and `cursorType` is used to control the cursor to be displayed within this `windowItem`.
- `drag` and `resize` are facilities to be used for interactive

manipulations of this windowItem.

canvas is the only windowItem subclass that allows attachment of other windowItems. In this respect, canvasses resemble windows (that uses a canvas to contain the windowItems of the window).

---

Lidskjalv - Reference Manual

[' Milner  
Informatics](#)

Chapter 1: The guienv Library

# Using the guienv Library

The Lidskjalv libraries consists of a number of BETA fragments, where the fragment guienv describes the basic patterns of the library.

The fragments control, fields, scrolllist, figureitems etc. contain additional facilities to those defined in guienv. This chapter and the next chapters gives a thorough description of each of these fragments. Along with the descriptions, examples are given to illustrate the intended use.

The guienv fragment consists of a single pattern guienv where the attributes of a graphical application are described. Patterns like window and menu are described inside guienv.

By specializing guienv, the user can develop a Lidskjalv application using the predefined patterns and objects in guienv.

A Lidskjalv application is invoked by executing an instance of the guienv specialization. Any Lidskjalv application must therefore have the following outline:

```
ORIGIN '~beta/guienv/guienv'
--- program: descriptor ---
guienv
  (# ...
  do ...
  #)
```

In order to reduce the complexity of simple applications, more advanced facilities of Lidskjalv are located in separate fragments. To utilize these facilities, the above outline of a typical Lidskjalv application must be augmented by specifying the additional facilities used. This is done by including the fragment containing the facility. The facilities are located in separate fragments, such as control, fields, scrolllist and figureitems. These fragments can be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/control'
--- program: descriptor ---
guienv
  (# ...
  do ...
  #)
```

where, in this case control, is the name of the desired fragment. If more than one additional facility is needed, the INCLUDE line is simply repeated with the names of the other fragments.

The basic pattern in guienv is interfaceObject, which is the common superpattern for all patterns describing interaction with the user.

When guienv executes inner, a global event handler is started. This event handler loops until the attribute terminate is executed. When an

event occurs, the global event handler distributes the event to the interfaceObject in question. It could be a menu or the active window.

---

Chapter 1: The guienv Library

# Examples of Use of the guienv Fragment

The demo programs in this manual can be found in the reference demo subdirectory in the guienv directory. The location of the directory in installation-dependent

~beta/guienv/demo/ReferenceDemos

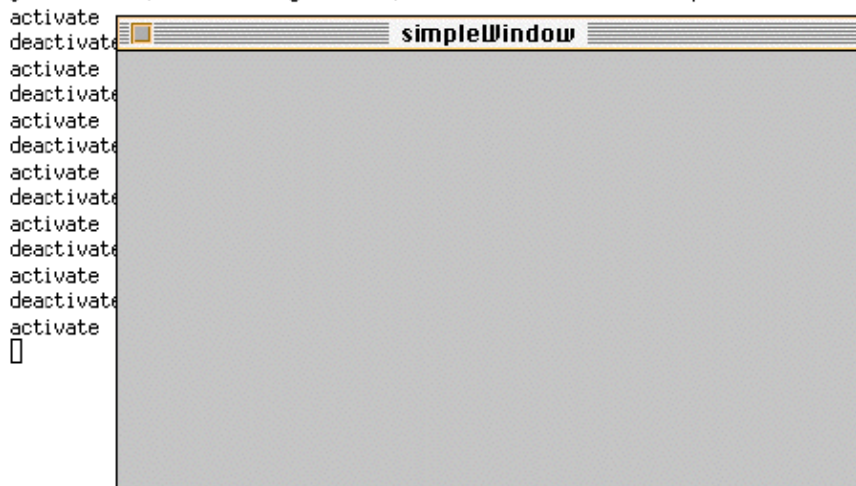

The demo directory contains many more demo programs than is included in this manual. Please inspect the demo directory for other illustrative demo programs. Appendix A contains a short overview of the demos in the demo directory.

This demo program is nearly the simplest possible Lidskjalv program. It opens one window and prints activate (resp. deactivate) each time the window is made active (resp. inactive).

## simplewindow.bet

```
ORIGIN '~beta/guienv/guienv';
(* This demo shows how to create a very simple window and it
 * illustrates the activate/deactivate event.
 *)
--- program: descriptor ---
guienv
(# simpleWindow: @window
  (# eventHandler::
    (# onAboutToClose:: (# do terminate #);
    onActivate::
      (# do 'activate' -> putline #);
    onDeactivate::
      (# do 'deactivate' -> putline #)
    #);
  open::
    (# do (400,400) -> size #)
  #)
do simpleWindow.open
#)
```

```
jlk@fraxirus:/users/beta/guienv/v1.3/demo/ReferenceDemos> simplewindow
```

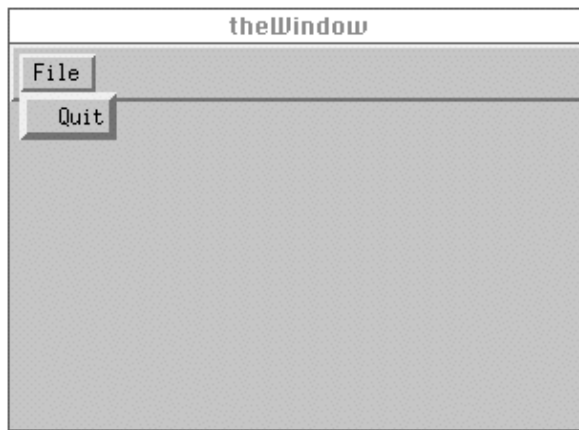

This demo program illustrates the use of standard menubar where the file menu only has one menuitem. It also illustrates how to further bind noMouseDown, onMouseDown and onKeyDown event patterns.

### windowWithStandardMenubar.bet

```

ORIGIN '~beta/guienv/guienv';
(* This demo shows how to create a simple window with a
 * standardMenubar where the file menu only has one menuitem. It also

## Chapter 2: The stddialogs Library

This fragment contains a few standard dialogs (more will be added later):

- `noteUser` which brings up a simple dialog with a message, and waits for the user to press the OK button.
- `alertUser`, similar to `noteUser`.
- `fileSelectionDialog` brings up a standard file selection dialog.
- `fileCreationDialog` brings up a standard create/save file dialog.

# Using the stddialogs Library

Remember that in order to utilize this extension to Lidskjalv, the fragment stddialogs must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/std dialogs'
--- program: descriptor ---
guienv(# ...
    do ...
        ... -> fileSelectionDialog -> ...;
        ...
#)
```

# Examples of Use of the stddialogs Fragment

This demo program illustrates the use of the standard file selection dialog. The name of the file selected in the dialog is printed on the screen.

## file.bet

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/std dialogs';
(* This demo shows how to use the fileSelectionDialog pattern. The
 * name of the file selected in the dialog is printed on the screen.
 *)
-- program: descriptor --
guienv
(# theWindow: @window
  (# eventHandler::
    (# onAboutToClose:: (# do terminate #);
    onMouseUp::
      (# name: ^text;
      do theWindow[] -> fileSelectionDialog -> name[];
      (if name[]=NONE then
        'Selected Cancel' -> putline
      else
        name[] -> putline
      if)
      #)
    #)
  #)
do theWindow.open
#)
```

## Chapter 3: The controls Library

The controls library contains a series of subpatterns of windowItem, intended primarily to be used in dialog boxes (e.g. buttons, check boxes, etc.).

These subpatterns are called controls, and the inheritance tree of controls in the controls library is:

To illustrate the facilities, we have included the Macintosh graphical elements associated with these classes. Naturally, the graphical elements will appear differently on the Motif and Win32 platforms:

Control pattern name	Image	Description
scrollbar		Used for various scrolling purposes.
staticText	<b>Paper:</b>	Used to specify permanent text in the dialog (usually explanatory text).
editText		Used to allow the user to enter some text.
pushButton		

A button is used to specify some actions to be taken.

optionButton

Used to specify a button with associated pop-up menu.

checkBox

A check box is usually used together with other check boxes to present the user with a group of non-exclusive options.

radioButton

A radio box is usually used together with other radio boxes to present the user with a group of exclusive options.

iconButton

An icon is used to show a minor picture in the dialog.

Control is the superclass of all classes in the controls hierarchy. Most facilities of this class are intended for the implementation of the subclasses, and not relevant for most users of Lidskjalv.

Scrollbars are dials which the user can control to specify a value between 0 and some maximum value. The scrollbar pattern has attributes for controlling the scroll step (scrollAmount) and the maximum value of the scrollbar (maxValue). The current value of the scrollbar can be obtained and changed by the value attribute.

The event handling of scrollbar defines several new events, e.g. onThumbMoved which is invoked when the scroll thumb have been moved by the user, and onPageUp which is invoked when the user presses the pageUp area in the scrollbar.

The orientation of the scrollbar is controlled by the vertical attribute (binding vertical to trueObject sets the orientation to vertical). The length of the scrollbar is manipulated through the length attribute.

EditText is a very single line text editor, primarily usable for small

amounts of text (such as file names etc.) in dialogs. The text must be in the same text style.

- style is used to specify the font information to be used for the text in this editText.
- contents is a reference to the text of this editText.

Button is the general superpattern for all controls that may act as buttons (i.e. react to menu button clicks), and may have a label associated with them.

Button has attributes for accessing and changing the label (label), and for accessing and changing the text style of the label (style).

- the events: onLabelChanged and onStyleChanged are invoked when the label or style have been changed.
- label is the text displayed in (or immediately along with) the button.
- style is used to define the font to be used when displaying the label.

PushButton is a simple button that reacts to mouse clicks. PushButton does not define additional attributes. The label of a pushButton is shown inside the button.

StaticText is a simple text label, and mostly used for informative text in dialogs and for labeling editText fields. StaticText does not define any additional attributes.

IconButton is a simple button with a icon defining its appearance. The label of an icon button may be shown centered below the icon, The showLabel attribute is used for controlling whether the label should be shown or not.

- the event: onShowLabelChanged is invoked when the label have been changed.
- showLabel is used to control whether the label should be displayed along with the icon.

An optionButton has an associated menu, that pops up when the user clicks at the optionButton. The button text of the optionButton is automatically updated to display the currently selected item in the menu. The currently selected menu item is accessible through the currentItem attribute. The menu connected to this optionButton is an instance of the menu pattern defined in guienv. The menu is connected through the popUpMenu attribute.

- the events: onCurrentItemChanged and onPopupMenuChanged are invoked when the a new item is selected in the associated menu, respectively when the menu is changed.
- popUpMenu is used to specify the menu to be popped up from this button.
- currentItem is the last selected menu item.

ToggleButton is the general superpattern for on/off buttons.

- the event: `onStateChanged` is used to specify the actions to be executed when the state of the `toggleButton` have been changed.
- `state` is used to control the state of this `toggleButton`.

RadioButton is a kind of `toggleButton` mostly used in a radio button cluster (several `radioButtons` of which only one can be on at any time - this must however be ensured by the application programmer in the current version). No additional attributes are defined.

CheckBox is mostly used for setting options in e.g. dialog boxes. Is intended to be used in checkbox groups. No additional attributes are defined.

DefaultButton is used for specifying the button to act as the default button (i.e. be activated by a carriage return). `DefaultButton` takes a reference to the button to be used as default as `enter` parameter. Currently not implemented on Motif.

# Using the controls Library

Remember that in order to utilize this extension to Lidskjalv, the fragment controls must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/controls'
--- program: descriptor ---
guienv(# pb: @pushButton;
      ...
      do ...
      ... -> pb.label;
      ...
      #)
```

# Examples of Use of the controls Fragment

This example illustrates how to create a window with two pushbuttons, and give a button a new size at runtime.

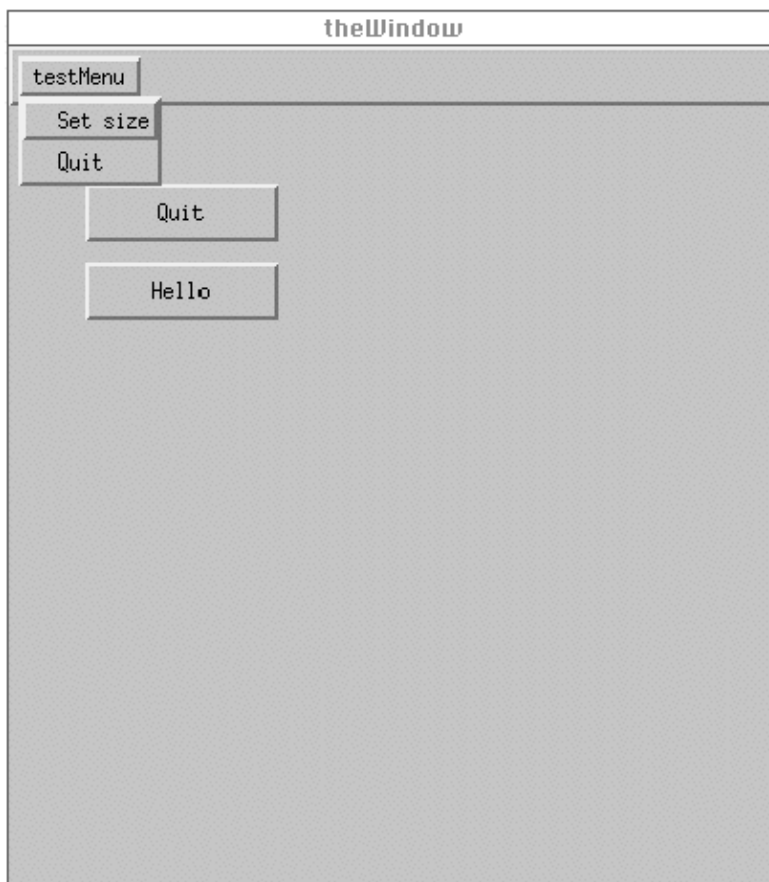

## button.bet

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/controls';

        helloButton.open;
        contents -> target
        #)
    #)
do theWindow.open
#)

```

## Chapter 4: The fields Library

The fields library contains five advanced subpatterns of `windowItem`. These patterns are used for displaying movies and editable text fields (with and without scrolling facilities), and for scrolling a group of `windowItems` using scrollbars.

`TextField` is an alternative to the `editText` control with extended facilities for cut/copy/paste, selection handling, etc. `TextField` contains many attributes supporting many different text editing functions: changing text style, deleting and inserting text, etc. Furthermore, `textField` has an additional event `onTextChanged` which will be invoked each time the text contents have been changed.

A readonly `textField` can be implemented simply by further binding the `onBeforeChange` virtual and here specify `false->allow`.

`TextField` takes care of most interaction with the user and many applications using `textField` need not do anything else but extract the text contents of the `textField` instance at the appropriate time.

`AbstractScroller` is a subpattern of `canvas` and implements a scrolling facility for any `windowItem` type (specified through the `contentsType` virtual attribute). An `abstractScroller` contains two scrollbars (one vertical and one horizontal), and the `windowItem` will scroll according to the manipulations of these scrollbars.

`TextEditor` is a subpattern of `abstractScroller` (with `contentsType` further bound to `textField`) and is an alternative to `textField`, offering additional scrolling facilities. `TextEditor` is a full-fledged text editor with full editing and scrolling. No additional attributes are defined.

`TextEditor` takes care of most interaction with the user and many applications using `textEditor` need not do anything else but extract the text contents of the `textEditor` instance at the appropriate time.

`Scroller` is another subpattern of `abstractScroller` (with `contentsType` further bound to `canvas`) that can scroll all `windowItems` attached to the `canvas`.

`MovieField` is intended for displaying video (not implemented yet).

# Using the fields Library

Remember that in order to utilize this extension to Lidskjalv, the fragment fields must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/fields'
--- program: descriptor ---
guienv(# te: @textEditor;
    ...
    do ...
    ... -> te..contents.selection;
    ...
#)
```

# Examples of Use of the fields Fragment

This demo program illustrates the facilities for constructing standard text editors.

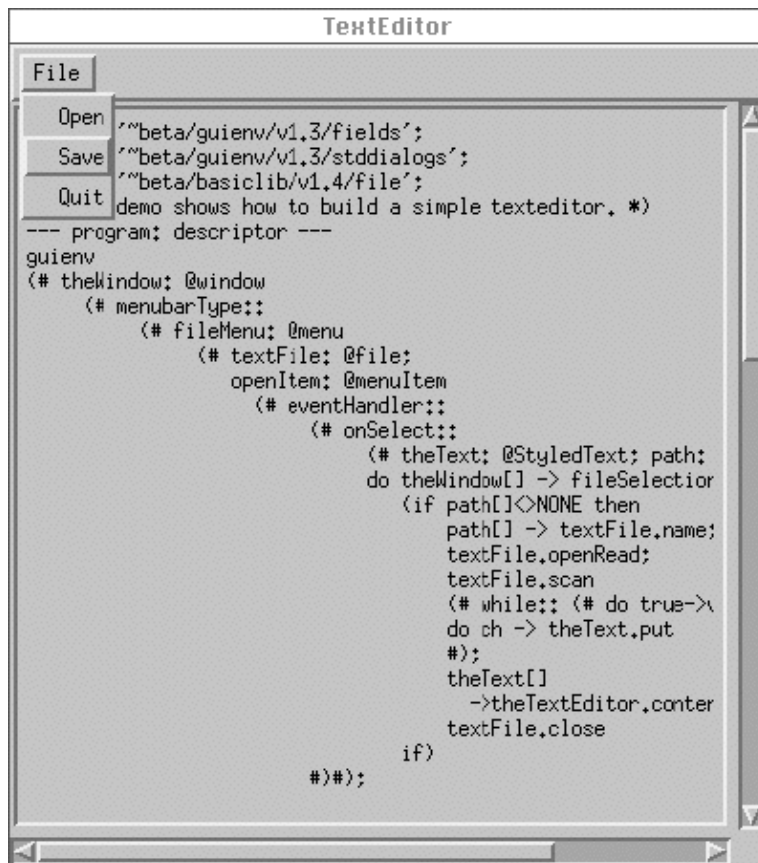

## texteditor.bet

```
ORIGIN '~beta/guienv/fields';
INCLUDE '~beta/guienv/stddialogs';
INCLUDE '~beta/basiclib/file';
(* This demo shows how to build a simple texteditor. *)
--- program: descriptor ---
guienv
(# theWindow: @window
  (# menubarType::
    (# fileMenu: @menu
      (# textField: @file;
        openItem: @menuItem
          (# eventHandler::
            (# onSelect::
              (# theText: @StyledText; path: ^text;
                do theWindow[] -> fileSelectionDialog -> path[];
                (if path[] <> NONE then
                  path[] -> textField.name;
                  textField.openRead;
                  textField.scan
                  (# while:: (# do true->value #);
                  do ch -> theText.put
                  #);

  (#
    do 'thetextEditor' -> title;
    (400,400) -> size;
    thetextEditor.open
  #)
#)
do theWindow.open
#)

```

## Chapter 5: The figureitems Library

The figureitems library is implementing a relative simple vector graphics system, sufficient for many purposes. For more advanced graphics, the Mjølner System contains a full-fledged 2D graphics library, called Bifrost (see [\[MIA 91-13\]](#) and [\[MIA 91-19\]](#)).

The vector graphics patterns are all subpatterns of figureItem. FigureItem is a subpattern of windowItem, and inherits all the event handling etc., allowing figureItems to react to user manipulations.

FigureItem is the general superpattern for all vector graphics patterns, implementing the common attributes of all graphics patterns. All figureItems have the attribute pen. Pen is an object used for drawing the figureItem. Pen has attributes for defining the drawing pattern of pen, for defining the foreground and background color of pen, and for defining the size (rectangle) of pen.

Line is used for drawing straight lines. The start and end attributes are used for controlling the starting (resp. ending) points of the line.

Shape is the general superpattern for all figureItems that can be filled with some paint. It defines one additional attribute, fill. Fill is an object used for modeling the properties of the paint used for filling the figureItem. Fill has attributes for defining the drawing pattern being used for the paint, and for defining the foreground and background color of the paint.

Oval and Rect are very similar in not defining any additional attributes.

RoundRect is similar to rect but with round corners. The roundness of the corners are defined as ovals and controlled through the roundness attribute.

Wedge defines a 'piece of cake' and defines startAngle and endAngle for controlling the wedge.

Polygon is a collection of points defining a connected set of straight lines. Polygon defines one additional attribute, points, used to control the points in the polygon.

# Using the figureitems Library

Remember that in order to utilize this extension to Lidskjalv, the fragment figureitems must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/figureitems'
--- program: descriptor ---
guienv(# 1: @line;
      ...
      do ...
        ps1 -> 1.start;
        ps2 -> 1.end;
      ...
      #)
```

# Examples of Use of the figureitems Fragment

This demo program is a little more elaborate. It is a simple draw editor in which you interactively can draw lines and polygons.

## draw.bet

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/figureitems';
(* This demo gives an example of how you can draw lines and polygons
 * with mouse using the figureitems "line" and "polygon". Clicking
 * with the left mouse button defines a node in the polygon/line,
 * clicking with the right mouse button ends the definition of the
 * polygon/line and draws it on the screen.
 *)
--- program: descriptor ---

## Chapter 6: The scrolllists Library

The scrolllists library contains two subpatterns of windowItem which implements scrolling lists:

ScrollList is a general superpattern realizing the basic functionality of displaying and scrolling in a list of equally sized elements (including facilities for managing single and multiple selections of the elements in the scrollList).

ScrollList contains attributes for inserting and deleting elements as well as for managing the selections (inserting, deleting, scanning and testing).

ScrollList is an abstract pattern that cannot be instantiated.

TextScrollList is a minor augmentation of scrollList to make support for scrolling lists of text elements. Adds three additional attributes: setText, getText and style, which allows for accessing and changing the text and the text style of the individual text elements in the scrollList.

# Using the scrolllists Library

Remember that in order to utilize this extension to Lidskjalv, the fragment scrolllists must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/scrolllists'
--- program: descriptor ---
guienv(# tsl: @textScrollList;
      ...
      do ...
        tsl.selection.first -> ...;
      ...
      #)
```

# Examples of Use of the scrolllists Fragment

This example illustrates how to use the textscrolllist windowItem.

## textscrolllist.bet

```
ORIGIN '~beta/guienv/guienv';

            v -> size;
            true -> bindBottom;
            true -> bindRight;
            5 -> append;
            theTextScrollList.numberOfItems -> noOfItems;
            (noOfItems-4,'Abraham Lincoln 1') -> setttext;
            (noOfItems-3,'Abraham Lincoln 2') -> setttext;
            (noOfItems-2,'Abraham Lincoln 3') -> setttext;
            (noOfItems-1,'Abraham Lincoln 4') -> setttext;
            (noOfItems,'Abraham Lincoln 5') -> setttext
```

```
        #)
    #);
open::
    (#
    do (400,400) -> size;
        theTextScrollList.open;
        theTextScrollList[] -> target
    #)
#)
do theWindow.open
#)
```

## Chapter 7: The graphmath Library

The graphmath library defines patterns for making graphical computations: point, rectangle, matrix, region, etc. Each of these patterns defines several operations.

- point is used for making calculations on 2D positions.
- rectangle is used for making calculations with 2D rectangles
- matrix is used for making calculations with coordinate system transformations.
- region is used for making calculations with 2D regions (i.e. areas in 2D, bounded by a polygon.) Please note that this pattern is not implemented yet.

# Using the graphmath Library

Remember that in order to utilize this extension to Lidskjalv, the fragment graphmath must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/graphmath'
--- program: descriptor ---
guienv(# p1, p2: @point;
    ...
do ...
    p1 -> p2.inset -> ...;
    ...
#)
```

# Examples of Use of the graphmath Fragment

This example gives an example of how to use the containsPoint operation of a rectangle.

## containspoint.bet

```
ORIGIN '~beta/guienv/guienv';
(* This demo gives an example of how to use the containsPoint
 * operation of a rectangle.
 *)
--- program: descriptor ---
guienv
(# theWindow: @window
  (# hitZone: @rectangle;
    open::
      (#
        do 'Graphmath Demo' -> title;
        (40,40) -> position;
        (300,300) -> size;
        ((0,0), (30,30)) -> hitZone
      #);
    eventHandler::
      (# onAboutToClose:: (# do terminate #);
        onMouseDown::
          (#
            do (if localPosition -> hitZone.containsPoint then
                'Mouse down in Hit Zone.' -> screen.putline
              if)
          #)
        #)
  #)
do theWindow.open
#)
```

## Chapter 8: The graphics Library

The graphics library is defining a simple drawing system (without any event handling facilities). Graphics is intended for lightweight drawings in canvasses, dialogs, etc., where user interaction with the drawings are not important.

Graphics defines a pen for controlling the color, size, etc. of the lines and points to be drawn. Furthermore, graphics defines several drawing operations, such as `moveTo`, `drawTo`, `drawSpot`, `drawLine`, etc.

# Using the graphics Library

Remember that in order to utilize this extension to Lidskjalv, the fragment graphics must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/graphics'
--- program: descriptor ---
guienv(# pm: @pixmap;
      ...
      do ...
      ... -> pm.read;
      ...
      #)
```

# Examples of Use of the graphics Fragment

This example illustrates reading a pixmap from a file and display it on the screen.

## drawbitmap.bet

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/graphics';
(* This demo is an example showing how read a bitmap from a file, and
 * using the graphics pattern to draw the bitmap on the screen.
 *)
--- program: descriptor ---
guienv
(# pm: @pixmap;
 theWindow: @window
  (# eventhandler::
   (# onAboutToClose:: (# do terminate #) #);
   obj: @windowItem
   (# open::
    (#
     do (50,50) -> position;
     (pm.width,pm.height) -> size
    #);
    eventHandler::
    (# onRefresh::
     (#
      do graphics
      (#
       do (pm[], (0, 0), (0, 0), pm.width,pm.height)
       -> drawRaster
      #)
     #);
    onMouseDown::
    (# do drag #)
   #)
  #);
 open::
  (#
   do (400,400) -> size;
   obj.open
  #)
 #)
do 'picture' -> pm.read;
(0xffff,0xffff,0xffff)->pm.transparentcolor;
theWindow.open
#)
```

## Chapter 9: The styledtext Library

The styledtext library is a very small library, implementing the interface to styled text (text in multiple fonts etc.). It is not intended for regular Lidskjalv users, since these facilities are more easily available through other patterns in Lidskjalv (e.g the text editors).

The styledtext library is only available on Macintosh versions. Future releases of Lidskjalv will include some styledtext library on all platforms, however, possibly with a different definition.

# Using the styledtext Library

Remember that in order to utilize this extension to Lidskjalv, the fragment styledtext must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/styledtext'
--- program: descriptor ---
guienv(# st: @styledText;
    ...
    do ...
    ... -> st.put;
    ...
#)
```

# Examples of Use of the styledtext Fragment

No demos, since this extension is not implemented yet.

---

Lidskjalv - Reference Manual

[Milner  
Informatics](#)

## Chapter 10: The guienvactions Library

As described in chapter 1, the event handling facilities in guienv includes facilities for attaching actions before and after the predefined actions of an interfaceObject. These actions are created as instances of the action pattern. However, in order to be able to access the informations related to the specific event, specialized action patterns are defined for each event type. These actions are defined in this library (and those described in chapter 12 and 13).

# Using the guenvactions Library

Remember that in order to utilize this extension to Lidskjalv, the fragment guenvactions must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/guenvactions'
--- program: descriptor ---
guienv(# beforeKeyDown: @keyDownAction
      (# do 'Hello' -> putText #);
      ...
do ...
  beforeKeyDown[] -> prependAction;
  ...
#)
```

# Examples of Use of the guenvactions Fragment

## Using keyboard actions

This demo program illustrates the action facilities by attaching actions to be executed before and after onKeyDown events in a edittext control.

### keyboardactions.bet

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/controls';
INCLUDE '~beta/guienv/guienvactions';
(* This demo shows how to prepend/append actions to keyDown events in
 * an editText control.
 *)
--- program: descriptor ---
guienv
(# theWindow: @window
  (# menubarType::
    (# testMenu: @menu
      (# quitItem: @menuItem
        (# open::
          (# do 'Quit' -> name #);
          eventHandler::
            (# onSelect::
              (# do terminate #)
            #)
          #);
        open::
          (# do quitItem.open; quitItem[] -> append #)
        #);
      open::
        (# do testMenu.open; testMenu[] -> append #)
      #);

## Chapter 11: The controlactions Library

The controlactions library defines the actions related to the events, related to the interfaceObjects, described in the control library.

# Using the controlactions Library

Remember that in order to utilize this extension to Lidskjalv, the fragment controlactions must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/controlactions'
--- program: descriptor ---
guienv(# lca: @labelChangedAction;
      ...
      do ...
        lca[] -> appendAction;
      ...
      #)
```

# Examples of Use of the controlactions Fragment

This example illustrates how to use the labelChangedAction to adjust the size of a pushButton to the length of its label.

## buttonactions.bet

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/controls';
INCLUDE '~beta/guienv/controlactions';
(* This demo shows how to use the labelChangedAction to adjust the
 * size of a pushButton to the length of its label. The action is
 * created by remote access to show that actions can be added without
 * specializing the button.
 *)
--- program: descriptor ---
guienv
(# theWindow: @window
  (# theLabelChanged: @aButton.labelChangedAction
    (# theTextStyle: ^textStyle; widthOfLabel: @integer;
      lw, lh: @integer
    do aButton.size -> (lw, lh);
    aButton.style -> theTextStyle[];
    aButton.label -> theTextStyle.widthOfText -> widthOfLabel;
    (if (lw < widthOfLabel + 6) then
      widthOfLabel + 6 -> lw
    if);
    (if (lh < theTextStyle.lineHeight + 2) then
      theTextStyle.lineHeight + 2 -> lh
    if);
    (lw, lh) -> aButton.size
  #);
  aButton: @pushButton;
  eventhandler::
    (# onAboutToClose:: (# do terminate #) #);
  open::
    (#
      do (40,40) -> position;
      (300,300) -> size;
      aButton.open;
      (10,10) -> aButton.position;
      (50,16) -> aButton.size;
      'Button1' -> aButton.label;
      theLabelChanged[] -> aButton.appendAction;
      'A Long Button Label' -> aButton.label
    #)
  #)
do theWindow.open
#)
```

## Chapter 12: The fieldsactions Library

The fieldsactions library defines the actions related to the events, related to the interfaceObjects, described in the fields library.

# Using the fieldsactions Library

Remember that in order to utilize this extension to Lidskjalv, the fragment fieldsactions must be included as follows:

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/fieldsactions'
--- program: descriptor ---
guienv(# bca: @beforeChangeAction;
    ...
    do ...
        bca[] -> appendAction;
    ...
#)
```

# Examples of Use of the fieldsactions Fragment

This example illustrates how a beforeChangeAction can be used to 'eat' every second keystroke in a textField.

## textfieldactions.bet

```
ORIGIN '~beta/guienv/guienv';
INCLUDE '~beta/guienv/fields';
INCLUDE '~beta/guienv/fieldsactions';
INCLUDE '~beta/guienv/controls';
(* This is a silly demo that shows how a beforeChangeAction can be
 * used to 'eat' every second keystroke in a textField.
 *)
--- program: descriptor ---
guienv
(# allowEdit: @boolean;
 theWindow: @window
  (# theTextField: @textField
   (# aBeforeChangeAction: @beforeChangeAction
    (# do not allowEdit -> allowEdit #);
   eventHandler::
    (# onBeforeChange::
     (# do allowEdit -> allow #);
    #);
   open::
    (#
     do true -> bindBottom -> bindRight;
     aBeforeChangeAction[] -> appendAction
    #)
   #);
  eventhandler::
  (# onAboutToClose:: (# do terminate #) #);
  open::
  (#
   do 'BeforeChangeAction Demo' -> title;
   (40,40) -> position;
   (300,300) -> size;
   true -> allowEdit;
   theTextfield.open;
   (300,300) -> theTextfield.size
  #)
 #)
do theWindow.open
#)
```

## Chapter 13: The guenvall Library

The guenvall library is a utility fragment, including all the Lidskjalv fragments. This library might be useful for the first-time user of Lidskjalv, since he then avoids being concerned with in which library a particular facility is defined. However, please remember, that using the guenvall library will increase your executable, since far to many facilities will be linked into your application.

# Using the guienvall Library

Remember that in order to utilize this extension to Lidskjalv, the fragment guienvall must be included as follows:

```
ORIGIN '~beta/guienv/guienvall';  
--- program: descriptor ---  
guienv(# pb: @pushButton;  
    ...  
    do ...  
    ... -> pb.label;  
    ...  
#)
```

## Chapter 14: The `guienvsystemenv` Library

The `guienvsystemenv` library is intended to be used by application, utilizing both `Lidskjalv` and concurrency. Please refer to the proper manuals for more information on the concurrency facilities.

# Using the guienvsystemenv Library

Remember that in order to utilize this extension to Lidskjalv, the fragment guienvsystemenv must be utilized as follows:

```
ORIGIN 'guienvsystemenv';  
--- program: descriptor ---  
systemEnv  
(# setWindowEnv::< (# do myWindowEnv[] -> theWindowEnv[] #);  
  myWindowEnv: @guienv (# ... #);  
  ...  
#)
```

Informatics](#)

.  
.

# Appendix A: Demo Programs

The demo programs in this manual can be found in the reference demo subdirectory in the guienv directory. The location of the directory in installation-dependent

`~beta/guienv/demo/ReferenceDemos.`

The demo directory contains many more demo programs than is included in this manual. Please inspect the demo directory for other illustrative demo programs. The following is a short description of the demos in the demo directory:

- `simplewindow.bet`

This demo shows how to create a very simple window and it illustrates the activate/deactivate event.

- `windowWithStandardMenubar.bet`

This demo shows how to create a simple window with a standardMenubar where the file menu only has one menuitem. It also illustrates how to further bind the onMouseDown, onMouseUp and onKeyDown event patterns.

- `file.bet`

This demo shows how to use the fileSelectionDialog pattern. The name of the file selected in the dialog is printed on the screen.

- `button.bet`

This demo shows how to create a window with two pushButtons, and how to give a button a new size on runtime.

- `texteditor.bet`

This demo shows how to build a simple texteditor.

- `draw.bet`

This demo gives an example of how you can draw lines and polygons with mouse using the figureitems line and polygon. Clicking with the left mouse button defines a node in the polygon/line, clicking with the right mouse button ends the definition of the polygon/line and draws it on the screen.

- `textscrolllist.bet`

This demo gives a simple example of how to use the textScrollList windowitem.

- `containspoint.bet`

This demo gives an example of how to use the containsPoint operation of a rectangle.

- `drawbitmap.bet`

This demo is an example showing how read a bitmap from a

file, and using the graphics pattern to draw the bitmap on the screen.

- iconbutton.bet

This demo shows how to use the pixmap pattern when creating an iconButton control. Each time you click in the window a new iconButton is created and positioned at the point where you click.

- keyboardactions.bet

This demo shows how to prepend/append actions to keyDown events in an editText control.

- buttonactions.bet

This demo shows how to use the labelChangedAction to adjust the size of a pushButton to the length of its label. The action is created by remote access to show that actions can be added without specializing the button.

- textfieldactions.bet

This is a silly demo that shows how a beforeChangeAction can be used to 'eat' every second keystroke in a textField.

## Appendix B: Implementation Design

The implementation design for the Lidskjalv framework mostly consists in selecting the widgets and gadgets for implementing the various Lidskjalv components. Below is a table, showing these correspondences for the three target platforms for Lidskjalv: Motif, Macintosh, and Windows (Win32 API).

### Lidskjalv Motif Macintosh Win32 API

interfaceObject

widget

superclass for menus, windows, controls, etc.

menuBar

RowColumn created as a menubar

menubar

Menubar

menu

RowColumn created as a menu

menu

Pop-up Menu

window

TopLevelShellWidgetClass

window

window

menuItem

CascadeButton/ PushButton/ ToggleButton

menuItem

menuItem

windowitem

DrawingArea

superclass for controls, texteditors, etc.

ChildWindow (except for figureItems)

canvas

simple specialization of Composite

object defining a local coordinate system with clipping

object defining a local coordinate system with clipping

scroller

ScrolledWindow

a canvas with scrollbars

a canvas with scrollbars

textEditor

ScrolledText

texteditor

MultiLine EDIT Control

control

simple specialization of Core

control (scrollbars, buttons, etc.)

CONTROL

button

simple specialization of Core

superclass for pushbutton, checkbox, etc.

Button Control

pushButton

PushButton

pushbutton

PushButton

iconButton

PushButton showing an image, but with a label

an icon with a name underneath (like the finder icons)

optionButton

OptionButton

popupmenu control

STATIC CONTROL + DROPDOWNLIST

staticText

Label

statictext item

Specialized window item

toggleButton

abstract class

superclass for checkbox and radiobutton

superclass for checkbox and radiobutton

radioButton

ToggleButton with indicatorType = ONE\_OF\_MANY

radiobutton

Button Control with BS\_RADIOBUTTON style

checkBox

ToggleButton with indicatorType = MANY\_OF\_MANY

checkbox

Button Control with BS\_CHECKBOX style

scrollbar

Scrollbar

scrollbar

## SCROLLBAR Control

editText

Text without scrollbars configured as a singleline field

edittext item (used for dialogs)

SingleLine EDIT Control

textField

Text without scrollbars configured as a multiline field

multiline textfield with no scrollbars

MultiLine EDIT Control

scrollList

abstract class

superclass for scrolllists

LISTBOX Control

textScrollList

List

scrolllist with one scrollbar, like in the standard file dialog

LISTBOX Control

**in interfaceObject:**

event

callback

callback functions called when different events occurs

callback functions called when different events occurs

action

eventHandler

callback functions called when different events occurs

callback functions called when different events occurs

open

init (XtCreateWiget/ XtManageChild)

creating and displaying the object

creating and displaying the object

close

destroy (XtDestroyWidget)

removing the object from the screen

removing the object from the screen

mouseDown

buttonPress

mouseDown

WM\_LBUTTONDOWN, WM\_MBUTTONDOWN, WM\_RBUTTONDOWN

mouseUp

buttonRelease

mouseUp

WM\_LBUTTONUP, WM\_MBUTTONUP, WM\_RBUTTONUP

**in menu:**

name

The LabelString of the CascadeButton the menu is connected to

The name of the menu, as it appears in the menubar

The name of the menu, as it appears in the menubar

**in window:**

refresh

exposure

update event

WM\_PAINT

target

keyBoardFocus

the object that handles the keydown events

the object that handles the keydown events

showModal

the window shown as SYSTEM\_MODAL

the window used as a modal dialog

the window used as an application modal dialog  
**in windowitem:**

position

x,y

the topleft corner of the objects bounding box

x,y

size

width,height

the width and height of the bounding box

nWidth,nHeight

bindLeft, etc.

geometry constraints in Form

resize constraints

resize constraints

show

map

show

SW\_SHOW

hide

unmap

hide

SW\_HIDE

 *
 * GUIENVSYSTEMENV
 * =====
 *
 * Use this fragment as the ORIGIN for concurrent programs
 * using the GUIENV libraries.
 *
 * The program should look something like:
 *
 * ORIGIN 'guienvsystemenv';
 * --- program: descriptor ---
 * systemEnv
 * (# setWindowEnv::< (# do myWindowEnv[] -> theWindowEnv[] #);
 *   myWindowEnv: @guienv (# ... #);
 *   ...
 * #)
 *
 * The 'setWindowEnv' virtual and 'theWindowEnv' reference are
 * declared in basicsystemenv.
 *
 * The guienv instance (myWindowEnv) assigned to theWindowEnv is
 * used for scheduling purposes to allow BETA coroutines to
 * cooperate with the event driven user interface.
 *
 * For concurrency details, see basicsystemenv.
 *)
